Python Pandas - Descriptive Statistics

A large number of methods collectively compute descriptive statistics and other related operations on DataFrame. Most of these are aggregations like sum(), mean(), but some of them, like sumsum(), produce an object of the same size. Generally speaking, these methods take an axis argument, just like ndarray. (sum, std, ...), but the axis can be specified by name or integer

• DataFrame - "index" (axis=0, default), "columns" (axis=1)

Let us create a DataFrame and use this object throughout this chapter for all the operations.

Example

Live Demo

```
import pandas as pd
import numpy as np
#Create a Dictionary of series
d = {'Name':pd.Series(['Tom','James','Ricky','Vin','Steve','Smith','Jack',
   'Lee', 'David', 'Gasper', 'Betina', 'Andres']),
   'Age':pd.Series([25,26,25,23,30,29,23,34,40,30,51,46]),
   'Rating':pd.Series([4.23,3.24,3.98,2.56,3.20,4.6,3.8,3.78,2.98,4.80,4.10,3.65])
#Create a DataFrame
df = pd.DataFrame(d)
print df
```

```
Name
               Rating
    Age
    25
                4.23
0
        Tom
                3.24
1
    26
        James
        Ricky
2
    25
                3.98
                2.56
        Vin
3
    23
        Steve
                3.20
4
    30
        Smith
                4.60
5
    29
                3.80
6
    23
        Jack
        Lee 3.78
7
    34
        David 2.98
8
    40
9
        Gasper 4.80
    30
        Betina 4.10
    51
10
11 46
       Andres 3.65
```

sum()

Returns the sum of the values for the requested axis. By default, axis is index (axis=0).

Its output is as follows -

```
Age 382
Name TomJamesRickyVinSteveSmithJackLeeDavidGasperBe...
Rating 44.92
dtype: object
```

Each individual column is added individually (Strings are appended).

axis=1

This syntax will give the output as shown below.

```
import pandas as pd
import numpy as np

#Create a Dictionary of series
d = {'Name':pd.Series(['Tom','James','Ricky','Vin','Steve','Smith','Jack',
    'Lee','David','Gasper','Betina','Andres']),
    'Age':pd.Series([25,26,25,23,30,29,23,34,40,30,51,46]),
    'Rating':pd.Series([4.23,3.24,3.98,2.56,3.20,4.6,3.8,3.78,2.98,4.80,4.10,3.65])
}

#Create a DataFrame
df = pd.DataFrame
df = pd.DataFrame(d)
print df.sum(1)
```

```
0 29.23
1 29.24
2 28.98
```

```
25.56
3
    33.20
4
5
    33.60
    26.80
    37.78
7
    42.98
8
9
    34.80
   55.10
10
   49.65
11
dtype: float64
```

mean()

Returns the average value

```
Age 31.833333
Rating 3.743333
dtype: float64
```

std()

Returns the Bressel standard deviation of the numerical columns.

Its output is as follows -

```
Age 9.232682
Rating 0.661628
dtype: float64
```

Functions & Description

Let us now understand the functions under Descriptive Statistics in Python Pandas. The following table list down the important functions -

Sr.No.	Function	Description
1	count()	Number of non-null observations
2	sum()	Sum of values
3	mean()	Mean of Values
4	median()	Median of Values
5	mode()	Mode of values
6	std()	Standard Deviation of the Values
7	min()	Minimum Value
8	max()	Maximum Value
9	abs()	Absolute Value
10	prod()	Product of Values
11	cumsum()	Cumulative Sum
12	cumprod()	Cumulative Product

Note – Since DataFrame is a Heterogeneous data structure. Generic operations don't work with all functions.

- Functions like **sum()**, **cumsum()** work with both numeric and character (or) string data elements without any error. Though **n** practice, character aggregations are never used generally, these functions do not throw any exception.
- • Functions like **abs()**, **cumprod()** throw exception when the DataFrame contains character or string data because such operations cannot be performed.

Summarizing Data

The **describe()** function computes a summary of statistics pertaining to the DataFrame columns.

Its output is as follows -

```
Rating
                Age
         12.000000
                         12.000000
count
         31.833333
mean
                          3.743333
std
         9.232682
                          0.661628
min
         23.000000
                          2,560000
25%
         25.000000
                          3.230000
         29.500000
50%
                          3.790000
75%
         35.500000
                          4.132500
         51.000000
                          4.800000
max
```

This function gives the **mean**, **std** and **IQR** values. And, function excludes the character columns and given summary about numeric columns. **'include'** is the argument which is used to pass necessary information regarding what columns need to be considered for summarizing. Takes the list of values; by default, 'number'.

- **object** Summarizes String columns
- **number** Summarizes Numeric columns
- all Summarizes all columns together (Should not pass it as a list value)

Now, use the following statement in the program and check the output -

```
import pandas as pd
import numpy as np

#Create a Dictionary of series
d = {'Name':pd.Series(['Tom','James','Ricky','Vin','Steve','Smith','Jack',
    'Lee','David','Gasper','Betina','Andres']),
    'Age':pd.Series([25,26,25,23,30,29,23,34,40,30,51,46]),
    'Rating':pd.Series([4.23,3.24,3.98,2.56,3.20,4.6,3.8,3.78,2.98,4.80,4.10,3.65])
}

#Create a DataFrame
df = pd.DataFrame
df = pd.DataFrame(d)
print df.describe(include=['object'])
```

Its output is as follows -

```
Name
count 12
unique 12
top Ricky
freq 1
```

Now, use the following statement and check the output -

Live Demo

	Age		Name
count	12.000000		12
unique	NaN	12	
top	NaN	Ricky	
freq	NaN	1	
mean	31.833333	NaN	3.74333
std	9.232682	NaN	0.661628
min	23.000000	NaN	2.560000
25%	25.000000	NaN	3.230000
50%	29.500000	NaN	3.790000
75%	35.500000	NaN	4.132500
max	51.000000	NaN	4.800000
